

# Configuring Build Types and Product Flavors in Android

Kaushal Dhruw

 @drulabs

 in/kaushal-dhruw

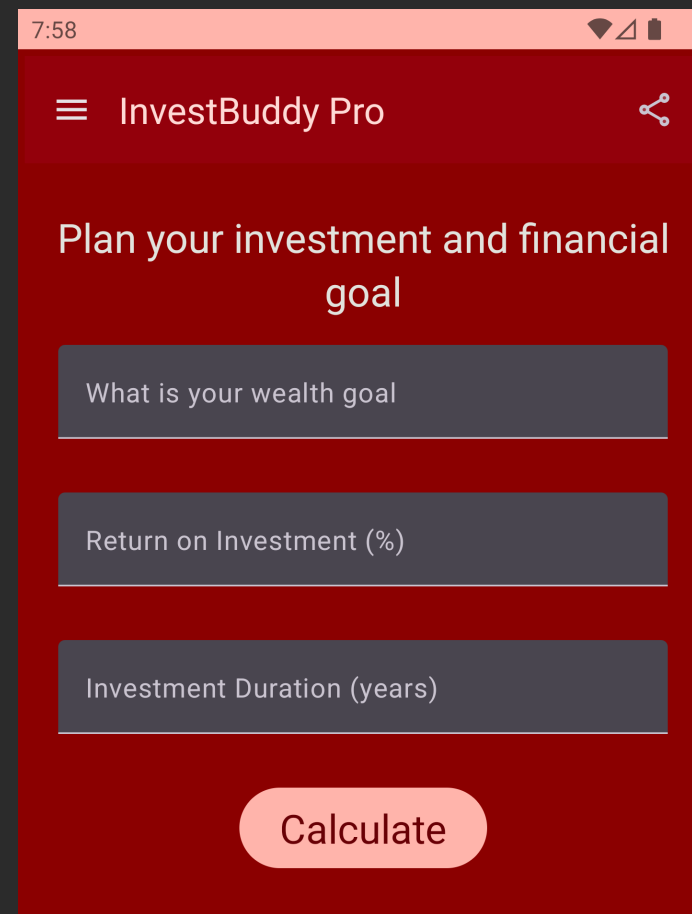

# Overview

- Why Product Flavors
- Explore **Built types**, **Product flavors** and **Build variants**
- Explore the **starter** project with white labelled demo app
- Create new **Build Type**, **Product Flavor** and **flavorDimension**
- Create **Build Variant** specific **color scheme** and **theming**
- **Coding Challenge**
- Add **Crashlytics** to individual Flavors
- When to use and when to avoid **Product Flavors**

# Why Product Flavors?

- Multi-Environment support
- Branding and Theming
- Build free and premium versions

Installment Duration (years)

Calculate

# Build Types

- Defines certain attributes to build the app
- “debug” and “release” build types are defined by default and can be configured
- “debug” build type uses debug key to sign the app
- “release” build type should be signed with the release key for distribution

# Build Types

- Refer to the existing build type type using `getByName("")`
- Create new build types
- New **build types** can be initialized with existing ones using `initWith`.
- `initWith` copies all properties from the given **build type**

```
buildTypes {  
    → getByName("debug") {  
        isMinifyEnabled = false  
    }  
    → getByName("release") {  
        isMinifyEnabled = true  
        proguardFiles(...)  
    }  
    create("alpha") {  
        initWith(getByName("debug"))  
        ...  
    }  
    create("beta") {  
        initWith(getByName("release"))  
        ...  
    }  
}
```

# Product Flavors and Dimensions

- Product flavors represent a versions of an app
- All product flavors share a common source
- Resources and code can be customized for each product flavor
- All product flavors must belong to a named flavor dimension
- You can define flavor specific gradle dependency.

# Defining Product Flavors

- We've been using **product flavors** all along
- **defaultConfig** belongs to **ProductFlavor** class
- Flavors can override any of the attributes of **defaultConfig** like **applicationId**
- **Product flavors** are combined with **Build Types** to create **build variants**

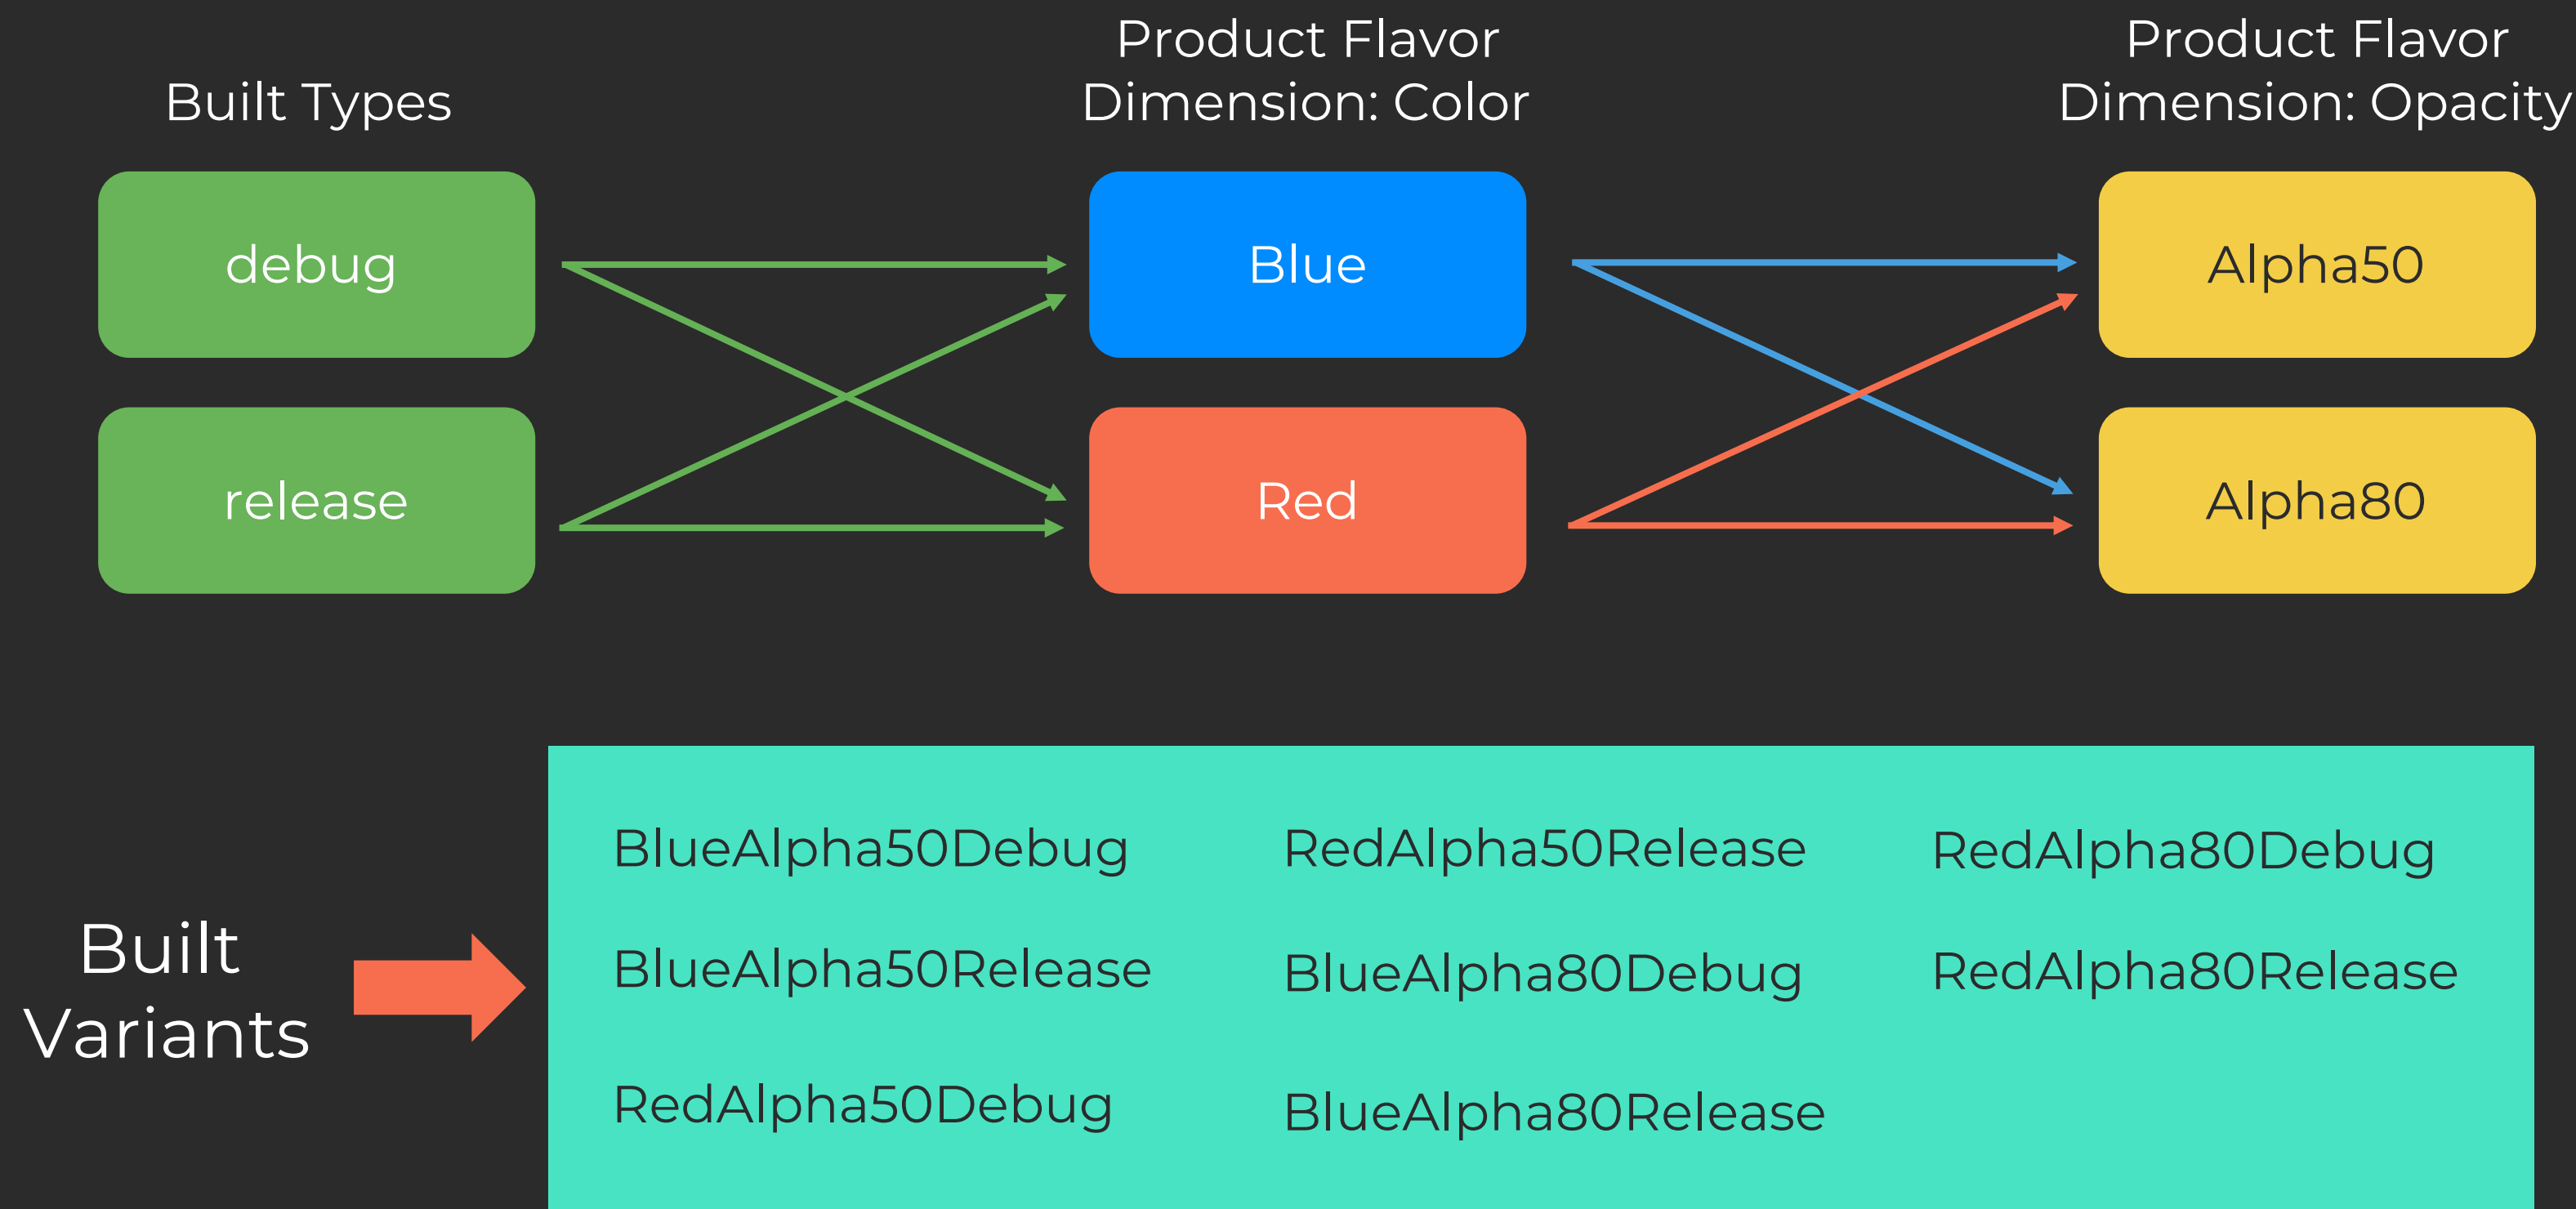

```
defaultConfig {  
    applicationId = "com.app.default"  
    targetSdk = 34  
    versionName = "3.2.1"  
    ...  
}
```

```
flavorDimensions += "color"
```

```
productFlavors {  
    create("red") {  
        dimension = "color"  
        applicationId = "com.app.red"  
        versionName = "1.0.8"  
    }  
    create("green") {  
        dimension = "color"  
        applicationId = "com.app.green"  
        versionName = "2.1.7"  
    }  
}
```

# Build Variant

# Demo

Wealthify: A white labelled app that calculates a Simple Interest based monthly premium for a target amount. Saves a few historical calculations.

- Explore existing product flavors
- Create dimension and product flavors
- Filter out unwanted flavors
- Flavor specific theming and customization
- Crashlytics integration

≡ WealthBuddy

Enter the values as suggested below to get started

Enter Amount  
40000

Rate of Interest (%)  
12

Tenure in years  
4

Calculate

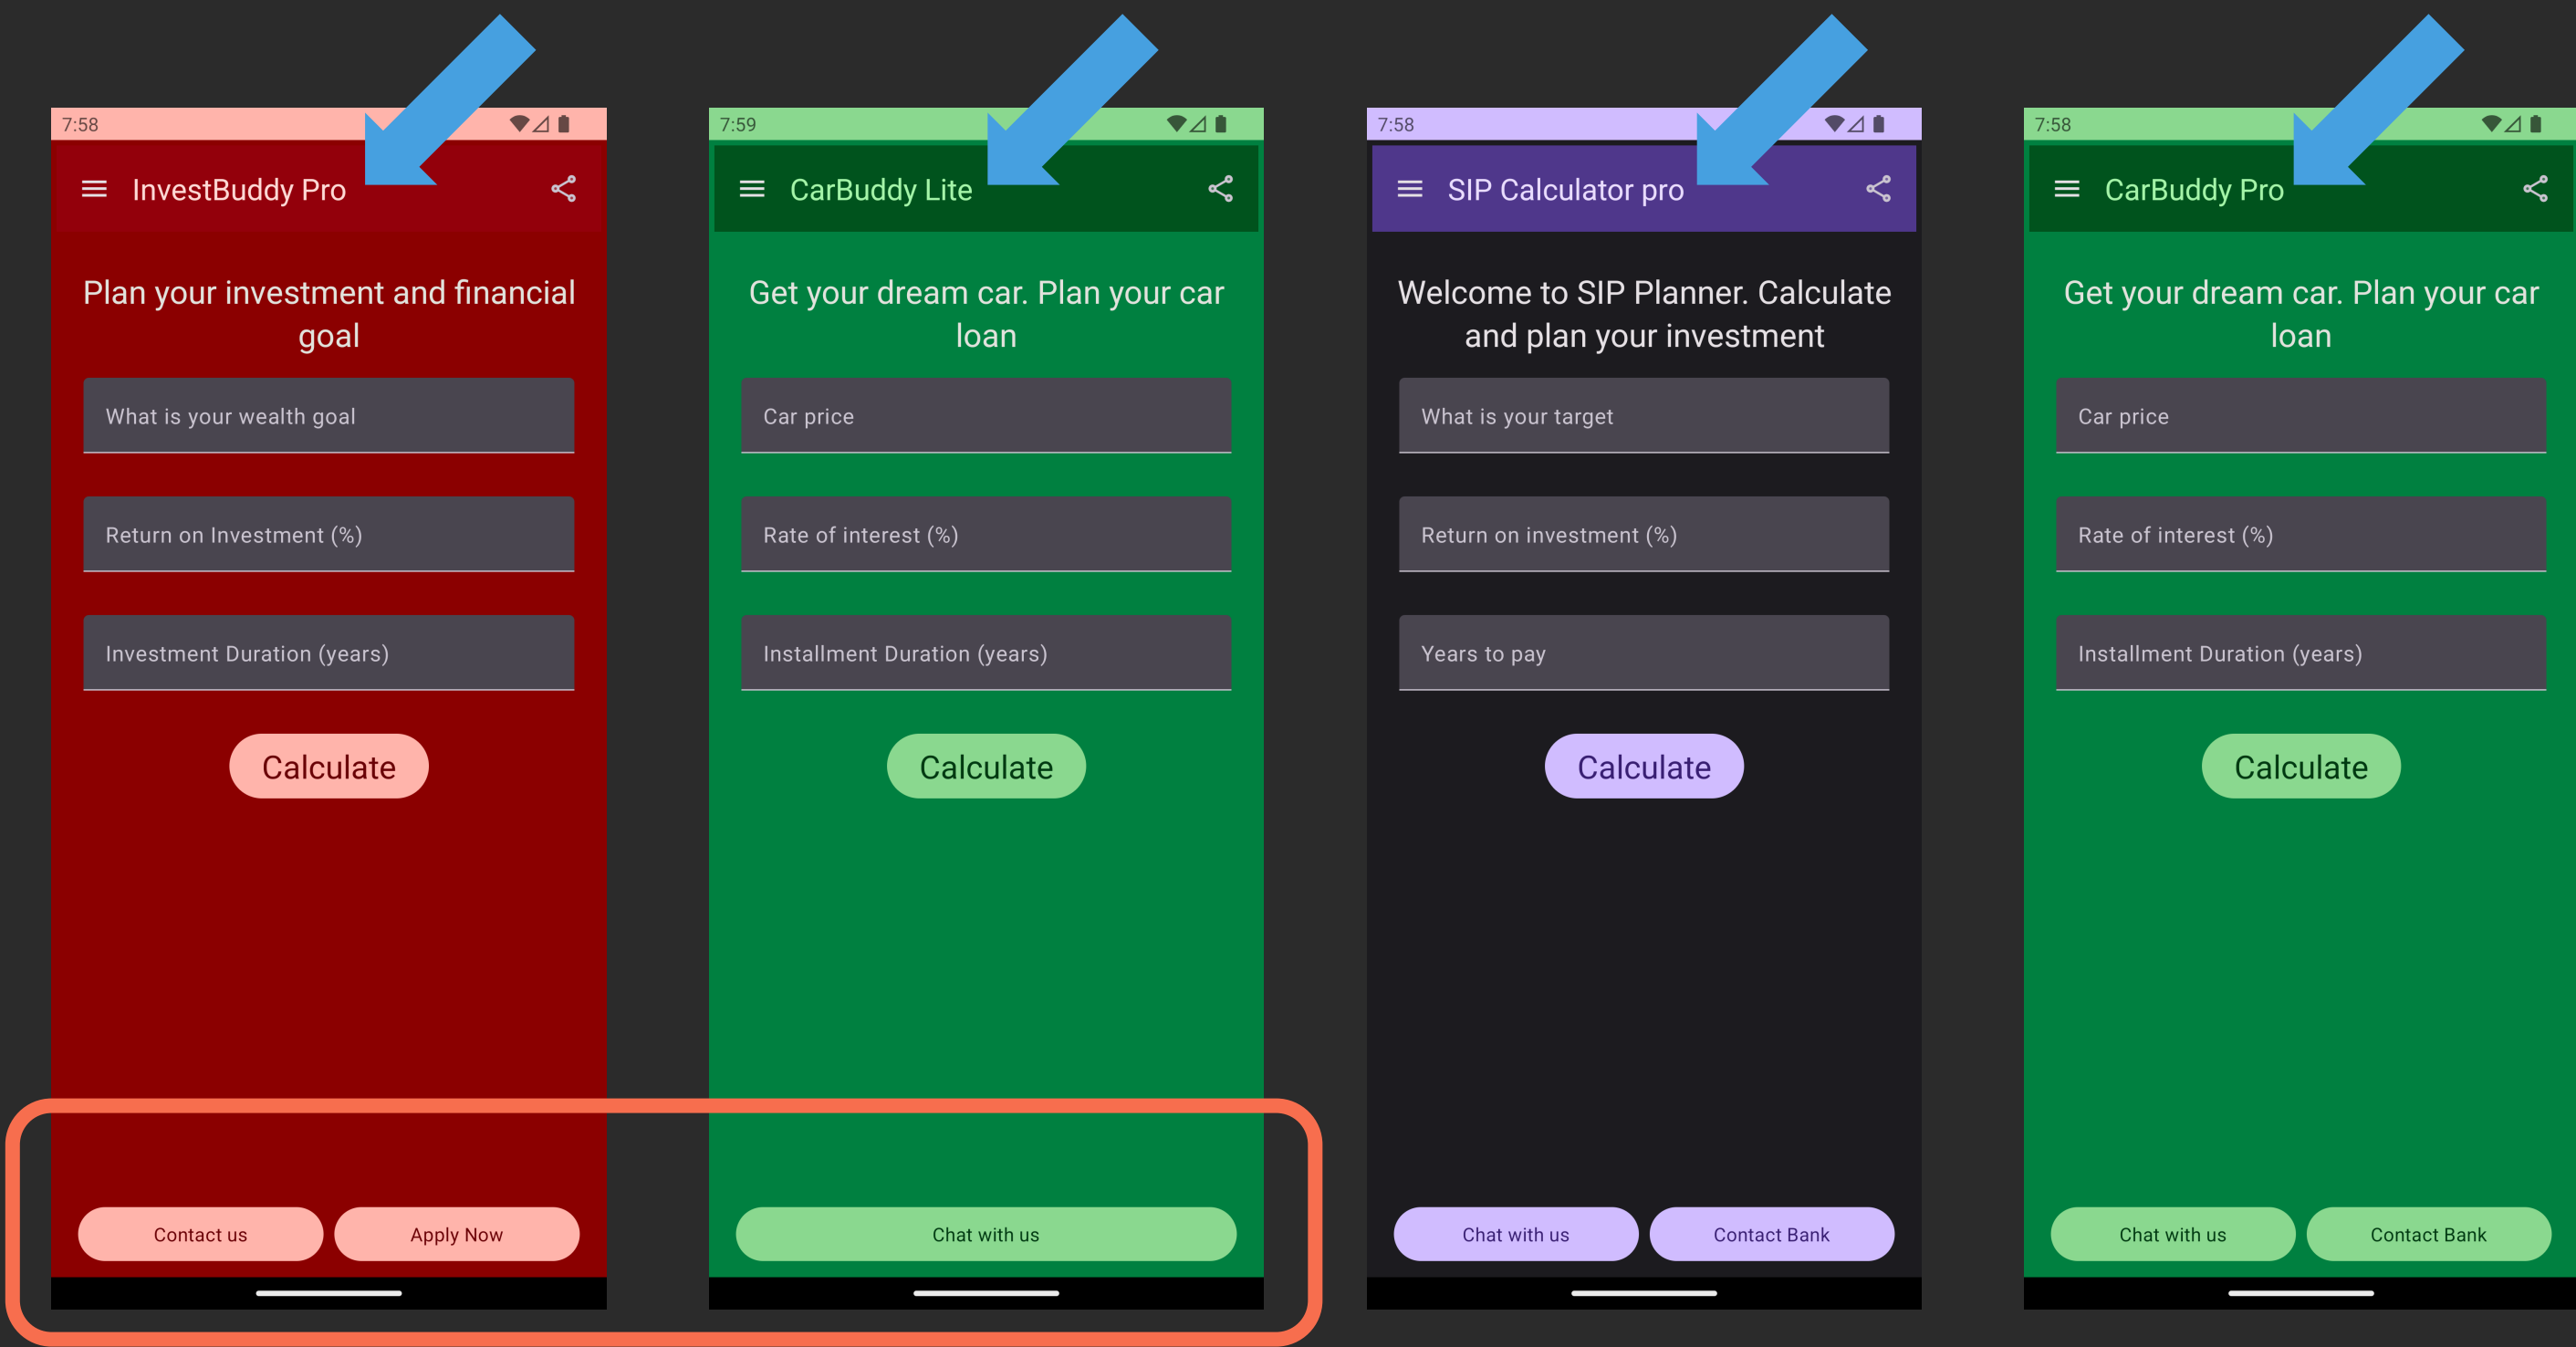

Amount = [27,027.03], Maturity amount = [40,000.00]  
Pay 563.06 monthly for 48 months

Connect with us

Apply

# Branding the White Labelled App

# Coding Challenge

- Create a new **Product flavor** called “investBuddy” under “customer” dimension
- Make sure to set the “isInvestment” build field to “true”
- You can get resources from the helper-files section of the repository
- Configure the apply and connect URLs to any new URLs
- Name the free and premium versions as “InvestBuddy Lite” and “InvestBuddy Pro” respectively.
- (optional) Add signing config for InvestBuddy variants

# Coding Challenge Solution

# When to Use and When NOT to

- Your app needs multiple variants
- Custom configuration like API endpoints
- Different testing environments
- Targeting different regions or market

- Your app is straightforward and very basic
- Versions differ too much in UI and implementation
- Limited audience

# Summary

- Explore **build types**, **product flavors** and **build variants**
- Create different versions of the white labelled demo app
- Create **build type** and **product flavors**
- Add **flavor specific** themes and resources
- Filter **product flavors**
- Extract fields into **BuildConfig** wherever applicable
- Integrate **Firebase** to various flavors
- When to use and when to avoid **product flavors**

# Thank You!!
